

Binary

Values of a String parameter containing the [@BINARY](#) attribute contain a binary data object and the name of the object (file name).

Besides the use for computed values (such as an Excel sheet), you can provide manual binary input by selecting the parameter in the knowledge browser and using the relevant options in the right mouse button menu (see also [QuaestorInterface](#)).

If you use expressions with the [EXCEL#](#) and [WINWORD\\$](#) function and your left term parameter contains the [@BINARY](#) attribute, the resulting document will be stored as binary in the parameter instead of the file name.
